# Outline

- 1 Modular polynomials, modular correspondences
- 2 Algebraic Theta Functions
- 3 Moduli space of abelian varieties with a  $\delta$ -marking
- 4 Modular correspondence in the space  $\mathcal{M}_\delta$
- 5 The image of the modular correspondence

# The modular polynomial

Let  $E$  be an elliptic curve with  $j$ -invariant  $j(E)$ . Let  $\ell$  be a positive integer and let  $\mathcal{S}_\ell$  be the set of isomorphism class of elliptic curves  $E'$  such that there exists a  $\ell$ -isogeny,  $E \rightarrow E'$ . We have the following theorem (see [Sil94] for instance):

## Theorem

*Let  $\ell$  be a positive integer,  $E$  an elliptic curve. There exists a polynomial  $\Phi_\ell(X, Y) \in \mathbb{Z}[X, Y]$  such that if  $j = j(E)$  is the  $j$ -invariant associated to  $E$  then*

$$\Phi_\ell(X, j) = \prod_{E' \in \mathcal{S}_\ell} (X - j(E')).$$

# Applications of the modular polynomial I

There exists numerous applications of modular polynomials in complex multiplication theory, point counting etc.

- Atkin and Elkies (see [Elk98]) take advantage of the modular parametrisation of  $\ell$ -torsion subgroups of elliptic curves in order to improve the original point counting algorithm of Schoof [Sch95].

# Applications of the modular polynomial II

- In [Sat00], Satoh has introduced an algorithm to count the number of rational points of an elliptic curve defined over a finite field  $k$  based on the computation of the canonical lift of the  $j$ -invariant of an elliptic curve  $E_k$ .
- It is possible to improve the original lifting algorithm of Satoh [VPV01, LL06] by solving over the  $p$ -adics an equation given by the modular polynomial  $\Phi_p(X, Y)$ .
- By considering generalisations of the modular polynomials, it is possible to improve the initialisation part of a quasi-quadratic point counting designed together with R. Carls [CL08].

# Modular polynomial and modular correspondence

- Denote by  $X_0(N)$  the modular curve which parametrizes the set of elliptic curves together with a  $N$ -torsion subgroup. For instance,  $X_0(1)$  is nothing but the projective line of  $j$ -invariants.

# Oriented modular correspondence

In order to improve the algorithm of Satoh, D. Kohel introduces the notion of oriented modular correspondence [Koh03].

## Definition

Let  $p$  be prime to  $N$ . A rational map of curves  $X_0(pN) \rightarrow X_0(N) \times X_0(N)$  is an oriented modular correspondence if the image of each point represented by a pair  $(E, G)$  where  $G$  is a subgroup of order  $pN$  of  $E$  is a couple  $((E_1, G_1), (E_2, G_2))$  with  $E_1 = E$  and  $G_1$  is the unique subgroup of index  $p$  of  $G$ , and  $E_2 = E/H$  where  $H$  is the unique subgroup of order  $p$  of  $G$ .

# Modular correspondence and modular polynomial

We explain the link between modular correspondences and the modular polynomial.

- In the case that the curve,  $X_0(N)$  has genus zero, the image of the correspondence is the locus defined by a binary equation  $\Phi(X, Y) = 0$  in  $X_0(N) \times X_0(N)$  cutting out a curve isomorphic to  $X_0(pN)$  inside the product.
- For instance, if one consider the oriented correspondence  $X_0(\ell) \rightarrow X_0(1) \times X_0(1)$  for  $\ell$  a prime number then the polynomial defining its image in the product is the modular polynomial  $\Phi_\ell(X, Y)$ .

## The higher genus case

For the higher genus case, a good definition of a moduli space is more subtle.

- We fix an integer  $g > 0$ . We consider set of triples of the form  $(A_k, \mathcal{L}, \Theta_{\bar{n}})$  where  $A_k$  is a  $g$  dimensional abelian variety over the field  $k$  equipped with a symmetric ample line bundle  $\mathcal{L}$  and a theta structure  $\Theta_{\bar{n}}$  of type  $\bar{n}$ .
- To a triple  $(A_k, \mathcal{L}, \Theta_{\bar{n}})$ , one can associate following [Mum66] its theta null point. The locus of theta null points is a quasi-projective variety  $\mathcal{M}_{\bar{n}}$ .

The theory of algebraic theta functions due to Mumford [Mum66], gives equations for the variety  $\mathcal{M}_{\bar{n}}$ .

# Algebraic theta functions

- In the analytic context, an abelian variety  $A$  is defined by the quotient of  $\mathbb{C}^g$  by a lattice  $\Lambda$ . The lattice  $\Lambda$  comes with a skew linear form  $H$  given by the polarization and a choice of a symplectic basis of  $\Lambda$  for  $H$  determines a matrix period  $\Omega$ . The matrix  $\Omega$  gives a unique projective embedding of  $A$  provided by the way of theta functions.
- In the algebraic context, the choice of a symplectic basis of  $\Lambda$  is replaced by something called a theta structure.

# Theta structure

- Let  $A_k$  be an abelian variety over  $k$ . Let  $\mathcal{L}$  be a degree  $d$  ample line bundle on  $A_k$ . There exists an isogeny  $\phi_{\mathcal{L}}$  from  $A_k$  onto its dual  $\hat{A}_k$  defined by  $\phi_{\mathcal{L}} : A_k \rightarrow \hat{A}_k$ ,  
 $x \mapsto \tau_x^* \mathcal{L} \otimes \mathcal{L}^{-1}$ . Denote by  $K(\mathcal{L})$  the kernel of  $\phi_{\mathcal{L}}$ .
- Let  $\delta = (d_1, \dots, d_l)$  be a finite sequence of integers such that  $d_i | d_{i+1}$ , we consider the finite group variety  $Z(\delta) = (\mathbb{Z}/d_1\mathbb{Z})_k \times_k \dots \times_k (\mathbb{Z}/d_l\mathbb{Z})_k$  with elementary divisors given by  $\delta$ . For a well chosen  $\delta$ , the finite group variety  $K(\delta) = Z(\delta) \times \hat{Z}(\delta)$  where  $\hat{Z}(\delta)$  is the Cartier dual of  $Z(\delta)$  is isomorphic to  $K(\mathcal{L})$  ([Mum70]).
- One may think of a theta structure  $\Theta_\delta$  as an isomorphism between  $K(\mathcal{L})$  and  $K(\delta)$ .

## Some properties of theta structures

- a theta structure determines a basis a global sections of  $\mathcal{L}$  labeled by  $Z(\delta)$  and as such a projective embedding  $\phi$  of  $A$  into  $\mathbb{P}_k^{Z(\delta)}$ .
- The point  $\phi(0)$  is called the theta null point defined by the theta structure  $\Theta_\delta$ .

# Marked Abelian varieties

- An Abelian variety with a marking is the data of a triple  $(A_k, \mathcal{L}, \Theta_\delta)$ ;
- A result of Mumford tells us that if  $\delta$  is large enough the locus of theta null points  $\mathcal{M}_\delta$  is a classifying space for the triples  $(A_k, \mathcal{L}, \Theta_\delta)$ .

One can see  $\mathcal{M}_\delta$  as a generalisation of the modular curve  $X_0(n)$ .

# Riemann Equations I

Equations for abelian varieties:

## Theorem

Denote by  $\hat{Z}(2)$  the dual group of  $Z(2)$ . Let  $(a_i)_{i \in Z(\delta)}$  be the theta null points associated to a triple  $(A_k, \mathcal{L}, \Theta_\delta)$  where  $4|\delta$ . For all  $x, y, u, v \in Z(2\delta)$  which are congruent modulo  $Z(\delta)$ , and all  $\chi \in \hat{Z}(2)$ , we have

$$\begin{aligned} & \left( \sum_{t \in Z(2)} \chi(t) \theta_{x+y+t} \theta_{x-y+t} \right) \cdot \left( \sum_{t \in Z(2)} \chi(t) a_{u+v+t} a_{u-v+t} \right) = \\ & = \left( \sum_{t \in Z(2)} \chi(t) \theta_{x+u+t} \theta_{x-u+t} \right) \cdot \left( \sum_{t \in Z(2)} \chi(t) a_{y+v+t} a_{y-v+t} \right). \end{aligned}$$

## Riemann Equations II

Equations for theta null points:

### Theorem

Denote by  $\hat{Z}(2)$  the dual group of  $Z(2)$ . Let  $(a_i)_{i \in Z(\delta)}$  be the theta null points associated to a triple  $(A_k, \mathcal{L}, \Theta_\delta)$  where  $4|\delta$ . For all  $x, y, u, v \in Z(2\delta)$  which are congruent modulo  $Z(\delta)$ , and all  $\chi \in \hat{Z}(2)$ , we have

$$\begin{aligned} & \left( \sum_{t \in Z(2)} \chi(t) a_{x+y+t} a_{x-y+t} \right) \cdot \left( \sum_{t \in Z(2)} \chi(t) a_{u+v+t} a_{u-v+t} \right) = \\ & = \left( \sum_{t \in Z(2)} \chi(t) a_{x+u+t} a_{x-u+t} \right) \cdot \left( \sum_{t \in Z(2)} \chi(t) a_{y+v+t} a_{y-v+t} \right). \end{aligned}$$

# Equations for $\mathcal{M}_\delta$

A theorem due to Mumford [Mum84] tells us that

## Theorem

*If  $8|\delta$ ,  $\mathcal{M}_\delta$  is an open sub-space of the projective variety defined by the homogeneous equations of theorem 4 together with the (symmetry) relations  $a_i = a_{-i}$  for all  $i \in Z(\delta)$ .*

## Modular correspondence in the space $\mathcal{M}_\delta$

We consider the following situation:

- Let  $\ell$  and  $n$  be relatively prime integers;
- let  $(A_k, \mathcal{L}, \Theta_{\overline{\ell n}})$  be a dimension  $g$  abelian variety together with a  $(\overline{\ell n})$ -marking.

The theta structure  $\Theta_{\overline{\ell n}}$  induces a decomposition of the kernel of the polarization

$$K(\mathcal{L}) = K_1(\mathcal{L}) \times K_2(\mathcal{L}) \quad (1)$$

into maximal isotropic subgroups for the commutator pairing associated to  $\mathcal{L}$ .

- Considering the preceding situation, there are two maximal isotropic  $\ell$ -torsion subgroups of  $K(\mathcal{L})$  compatible with the decomposition (1), say  $K_1(\mathcal{L})$  and  $K_2(\mathcal{L})$ ;
- Let  $\pi : A_k \rightarrow B_k$  be the isogeny defined by  $K_1(\mathcal{L})$  and  $\pi' : A_k \rightarrow B_k$  be the isogeny defined by  $K_2(\mathcal{L})$ .

## A diagram

We have the following diagram

## Modular correspondence in the theta setting

Keeping the notations from above, one can show that

- one can descend the  $(\ell\bar{n})$ -marking of  $A_k$  to  $(\bar{n})$ -markings of  $B_k$  and  $C_k$ ;
- as a consequence we have a well defined modular correspondence

$$\Phi_\ell : \mathcal{M}_{\ell\bar{n}} \rightarrow \mathcal{M}_{\bar{n}} \times \mathcal{M}_{\bar{n}}. \quad (2)$$

# Relation with theta null points I

## Proposition

*Let  $(A_k, \mathcal{L}, \Theta_{\overline{\ell n}})$  and  $(B_k, \mathcal{L}_0, \Theta_{\overline{n}})$  be defined as above. Let  $(a_u)_{u \in Z(\overline{\ell n})}$  and  $(b_u)_{u \in Z(\overline{n})}$  be theta null points respectively associated to  $(A_k, \mathcal{L}, \Theta_{\overline{\ell n}})$  and  $(B_k, \mathcal{L}_0, \Theta_{\overline{n}})$ . Considering  $Z(\overline{n})$  as a sub-group of  $Z(\overline{\ell n})$  via the map  $x \mapsto \ell x$ , there exists a constant factor  $\omega \in \overline{k}$  such that for all  $u \in Z(\overline{n})$ ,  $b_u = \omega a_u$ .*

## Relation with theta null points II

### Proposition

Let  $(A_k, \mathcal{L}, \Theta_{\bar{\ell}n})$  and  $(C_k, \mathcal{L}_0, \Theta_{\bar{n}})$  be defined as above. Let  $(a_u)_{u \in Z(\bar{\ell}n)}$  and  $(c_u)_{u \in Z(\bar{n})}$  be the theta null points respectively associated to  $(A_k, \mathcal{L}, \Theta_{\bar{\ell}n})$  and  $(C_k, \mathcal{L}_0, \Theta_{\bar{n}})$ . We have for all  $u \in Z(\bar{n})$ ,

$$c_u = \sum_{t \in Z(\bar{\ell})} a_{u+t}, \quad (3)$$

where  $Z(\bar{n})$  and  $Z(\bar{\ell})$  are considered as subgroups of  $Z(\bar{\ell}n)$  via the maps  $j \mapsto \ell j$  and  $j \mapsto nj$ .

# The image of the modular correspondence I

- Let  $\mathcal{C}$  be the reduced sub-variety of  $\mathcal{M}_{\bar{n}} \times \mathcal{M}_{\bar{n}}$  which is the image of  $\Phi_\ell(\mathcal{M}_{\bar{\ell}n})$ ;
- on geometric points  $\Phi_\ell$  is given by
$$(\mathbf{a}_u)_{u \in Z(\bar{\ell}n)} \mapsto ((\mathbf{a}_u)_{u \in Z(\bar{n})}, (\sum_{t \in Z(\bar{\ell})} \mathbf{a}_{u+t})_{u \in Z(\bar{n})}).$$

## The image of the modular correspondence II

- Let  $\pi_1$  (resp.  $\pi_2$ ) the restriction to  $\mathcal{C}$  of the first (resp. second) projection from  $\mathcal{M}_{\bar{n}} \times \mathcal{M}_{\bar{n}}$  into  $\mathcal{M}_{\bar{n}}$ ;
- Question: how to compute the algebraic set  $\pi_2(\pi_1^{-1}((b_u)_{u \in Z(\bar{n})}))$ ?

This question is the analog in our situation of the computation of the solutions of the equation  $\Phi_\ell(j, X)$ .

# Computation of the modular correspondence I

- First, we compute  $\pi_1^{-1}((b_u)_{u \in Z(\bar{n})})$ .
- Let  $(a_u)_{u \in Z(\bar{n})}$  be a geometric point in  $\pi_1^{-1}((b_u)_{u \in Z(\bar{n})})$  then we know that  $(a_u)$  satisfy the Riemann equations.

## Computation of the modular correspondence II

Let  $I$  be the ideal of the multivariate polynomial ring  $k[x_u | u \in Z(\overline{\ell n})]$  which

- spanned by the Riemann relations,
- the symmetry relations  $x_u = x_{-u}$ ,
- and the specialisation  $x_u = b_u$  if  $u \in Z(\overline{n})$ .

Denote by  $V_I$  the affine algebraic variety defined by  $I$ .

## Two results

Two results (obtained with Carls [CL08]):

- $V_l$  is a 0-dimensional algebraic variety;
- Taking some well chosen subset of the coordinates  $(a_u)_{u \in Z(\overline{\ell n})}$ , we obtain the coordinates of the point of  $\ell$ -torsion of  $B$  in the projective model given by  $\Theta_{\overline{n}}$ .

# Solving an algebraic system I

- The dominant step in computing the image of the modular correspondence is the computation of the solutions of the algebraic system determined by  $I$ .
- This can be done using a general purpose Groebner basis algorithm but it's painful.
- For instance, the system corresponding to the case genus 2 and  $\ell = 3$  it takes something like 25 hours and 8Go of memory using the F4 implementation of Magma on an average computer.

## Solving an algebraic system II

- We know that  $I \subset k[x_1, \dots, x_n]$  is a zero dimensional ideal generated by the polynomials  $[f_1(x_1, \dots, x_n), \dots, f_m(x_1, \dots, x_n)]$  where  $f_i$  is a polynomial in  $k[x_1, \dots, x_n]$ .
- We know more over that we can split the set of variables into two sets  $[x_1, \dots, x_n] = [x_1, \dots, x_k] \cup [x_{k+1}, \dots, x_n] = X \cup Y$  such that  $J = I \cap k[x_{k+1}, \dots, x_n] = I \cap k[Y]$  contains low degree polynomials.

## Solving an algebraic system II

- Taking into account the previous remarks one can design a special purpose Groebner basis algorithm;
- The main idea of the algorithm is : using a specific algorithm, we compute a truncated Groebner basis for an elimination ordering and a modified graduation. This allows us to obtain an zero dimensional ideal  $J_1$  contained in  $J$ .

# Benchmarks I

- $k$  is the ground field,  $k' \supset k$  is the field extension.
- $T$  is the total CPU time (in seconds) for the whole algorithm.
- $T_{\text{Gen}}$  is the time for generating the equations (Magma).
- $T_{\text{Grob}}$  is the sum of the Groebner bases computations (FGb and Magma).
- $T_{\text{Fact}}$  is the sum of the Factorization steps (Magma).
- $T_1$  is the total time of the algorithm excluding generating the equations:  $T_1 = T - T_{\text{Gen}}$ .

## Benchmarks II

$k$	$k'$	$T_{\text{Gen}}$	$T_{\text{Grob}}$	$T_{\text{Fact}}$	$T_1$	$T$
$5^{50}$	$5^{100}$	1.9	2.7	9.3	12	14
$5^{70}$	$5^{140}$	3.4	3.3	16.0	19	23

$3^{3000}$	$3^{6000}$	11219.9	396.3	3229.6	3704	14923

## Next thing to do

- A general way to compute isogenies (work in progress with D. Robert);
- Compute modular correspondences for bigger  $\ell$  (also work in progress with D. Robert).

The end.
